Salmonella-based Rodenticides and Public Health

John A. Painter,* Kåre Mølbak,*† Jacob Sonne-Hansen,† Tim Barrett,* Joy G. Wells,* and Robert V. Tauxe*

Several countries still permit strains of Salmonella enterica serotype Enteritidis, a leading cause of gastrointestinal illness in humans, to be used in rat baits. To assess the human health risk associated with such rat bait, we first reviewed historic data on health hazards associated with Ratin, a rodenticide that was used in Europe until the early 1960s. Ratin caused outbreaks of human illness, including several deaths. We then compared S. Enteritidis isolated from a current commercial product, Biorat, with S. Enteritidis from Ratin and found that the strains were both phage type 6a. Based on the similarity of the strains, currently available Salmonella-based rodenticides likely are as great a threat to public health as past strains were. Health officials should be aware that the continued use of Salmonella-based rodenticides is a risk to public health and should take appropriate measures to prevent use in their jurisdictions.

Salmonella enterica serotypes Typhimurium and Enteritidis have been used as rodenticides since the late nineteenth century. This use was explored after S. Typhimurium was discovered during a lethal epizootic in a research mouse colony (1,2). Researchers soon realized that the strains of S. Typhimurium used as rodenticide were identical to strains causing “meat poisoning” and might cause disease among humans. Use of S. Typhimurium rodenticides was discontinued early in the twentieth century, but S. Enteritidis continued to be used as a rodenticide in the United Kingdom and Denmark until the early 1960s. In 1954 (3) and again in 1967 (4), the World Health Organization (WHO) recommended that Salmonella-based rodenticides not be used because they posed a hazard to human health.

In spite of these recommendations, Salmonella-based rodenticides are still produced and used in Central America, South America, and Asia (2,5). Biorat (Labiofam, Cuba), one Salmonella-based rodenticide that is currently used in several countries (6,7), is made by coating rice grains with a combination of S. Enteritidis and warfarin. Currently, the Biorat product label offers no warning regarding the risk for human salmonellosis. Indeed, product information indicates that this product contains a strain of Salmonella that is pathogenic to animals but not to humans (7).

In 1995, the Centers for Disease Control and Prevention (CDC) received a sample of Biorat that had been distributed in Nicaragua (2), and in July 2001, U.S. custom authorities seized a shipment of Biorat destined for distribution in the United States. These incidents prompted us to compare Biorat with Ratin, one of the major Salmonella-based rodenticides used before the early 1960s; in addition, we summarize the public health hazards of Salmonella-based rodenticides.

Microbiologic Findings

We compared three isolates of S. Enteritidis recovered from Salmonella-based rodenticides. Two isolates (of the Biorat strain) were from Biorat samples collected in 1995 and 2001. The label from the Biorat product obtained in 2001 states that Biorat contains 1.25% “monopathogenic” Salmonella and 0.02% hydroxycoumarin. Pooled samples of the 1995 Biorat product yielded $1 \times 10^8$ CFU S. Enteritidis per gram of Biorat granules, and the 2001 product yielded 200,000 CFU per gram. A third isolate, S. Enteritidis var. Danysz (of the Ratin strain) was recovered from Ratin by the Danish Veterinary Laboratory in the 1920s or early 1930s.

Isolates were serotyped and biochemically characterized (8), subtyped by pulsed-field gel electrophoresis (PFGE) with the restriction enzymes XbaI and BlnI (9), and phage-typed. Phage-typing was performed at the National Laboratory for Enteric Pathogens, National Microbiology Laboratory, Canadian Science Centre for Human and Animal Health.

Both the Biorat strains and the Ratin strain were identified as S. Enteritidis, phage type (PT) 6a. The two Biorat strains were indistinguishable from each other by PFGE with the restriction enzymes XbaI and BlnI. PFGE patterns of the Ratin strain differed from those of the Biorat strain by three bands with XbaI and by five bands with BlnI (Figure 1).

*Centers for Disease Control and Prevention, Atlanta, Georgia, USA; and †Statens Serum Institut, Copenhagen, Denmark
Neither the Biorat strains nor the Ratin strain was shown to decarboxylate lysine. By contrast, four S. Enteritidis PT 6a isolates in the CDC culture collection from sources unrelated to Biorat or Ratin were positive for lysine decarboxylase. Thrall et al. reported that the strain of S. Enteritidis PT 6a from Biorat is indistinguishable from those of the Ratin and Liverpool rodenticide strains by plasmid profile typing (5), as both strains contained plasmids of approximately 59, 4.0, and 3.0 MDa.

Public Health Hazard

Since the mid 1980s, S. Enteritidis has caused a global pandemic of foodborne illness associated with eggs and poultry as a result of infection of the internal organs of chicken (10). Because of this pandemic, S. Enteritidis has become the most common serotype of Salmonella isolated from humans worldwide (11).

The S. Enteritidis strain found in Biorat is similar to the strain found in Ratin, a discontinued European product that caused human illness. Both strains were the same phage type, were indistinguishable by plasmid profile typing, and were different from 97% of salmonellae (8) in that they did not decarboxylate lysine. Although differences were noted between PFGE patterns of the Biorat strain and the Ratin strain, the similarities suggest that they may have originated from a common strain. Because the strains are similar and no evidence shows that the Biorat strain has decreased virulence, the Biorat strain is likely as pathogenic to humans as the Ratin strain.

In a retrospective study in Denmark from 1926 through 1956, Martin Kristensen identified 122 patients infected with the Ratin strain (12 and unpub. data), including 5 (4%) who died, 3 of whom were children. Twenty-two (18%) of 122 patients were reported to have eaten food items contaminated with Ratin, while 43 (35%) had handled the rodenticide. In 1956, Taylor (13) also reported several outbreaks of food poisoning associated with S. Enteritidis rodenticides and concluded that the use of bacterial rodenticides should be stopped.

Rodenticides containing salmonellae were evaluated during a plague outbreak in San Francisco in 1895 (2); they were found to have no definable impact on the rodent population, but they caused illness and death in humans who prepared and handled them. In 1921, Willfuhr and Wendtland (14) reported several outbreaks of human Salmonella infections from rodenticides. In one of these outbreaks, Russian prisoners of war who ate a large number of Ratin potato baits became ill, and two died. In another outbreak in 1918, two persons died and approximately 35 became ill after eating a cake that had been intentionally contaminated with Ratin (14,15). From 1920 through 1940, other outbreaks associated with Salmonella-based rodenticides were reported, and several of these outbreaks included deaths (15–18).

The Biorat product insert, as well as information available on the Internet (6,7), claims that the product is not harmful to humans and does not contaminate the environment. Recent newspaper articles have generated interest in using Salmonella-based rodenticides as an alternative to chemical rodenticides. Advocates for the use of Biorat claim, “[Biorat] has absolutely no secondary effects on other animals, on the environment, or on humans…. It contains a strain of Salmonella that only affects rats” (19).

S. Enteritidis causes severe diarrheal illness, which can be life-threatening, especially among children, the elderly, and immunocompromised persons. We have not identified any peer-reviewed, scientific data on the safety of Salmonella-based rodenticides, and to our knowledge, all strains of S. Enteritidis are capable of causing human illness. Noting the hazards of Salmonella-based rodenticides, many countries have banned their use, and WHO has repeatedly recommended against use of salmonellae in rodenticides.

Current concerns about bioterrorism suggest an additional public health threat posed by a commercially available strain of S. Enteritidis. Salmonella-based rodenticides have already been used intentionally to cause human illness (14,15); however, human illness may more commonly be caused by inadvertent exposure to Salmonella-based rodenticides. These rodenticides are generally mixed with grains to form baits (Figure 2). Biorat, for example, is made with whole rice and can easily be mistaken for food. Ingesting a few grams of bait, with at least 200,000 CFU per gram, could easily cause a severe case of salmonellosis.

To determine why Salmonella-based rodenticides are
still used despite information about the public health hazards, we conducted a literature search with the keywords “Salmonella” and “rodenticide” (National Library of Medicine, http://www.ncbi.nlm.nih.gov). We found 10 articles, in addition to the recent public health publications discussed above (2,5); none addressed the public health hazards of Salmonella-based rodenticides. Many of the reference materials we used to prepare the present article were not written in English or were not retrievable from current electronic databases. The continued use of Salmonella-based rodenticides may likely be related to the fact that the content of important but dated scientific papers is unlikely to be known to current decision-makers.

Salmonella-based rodenticides may contain an approved rodenticide, such as warfarin, in concentrations high enough to kill rats, and the addition of S. Enteritidis has not been shown to increase the effectiveness of the poison (2). Extensive use of Salmonella-based rodenticides in the past may have increased the prevalence of Salmonella in rodents (1) and consequently increased the potential for human salmonellosis by transmission from rodents to food or food animals. Unfortunately, a misperception exists that some strains of S. Enteritidis are not pathogenic to humans. We recommend informing rodent-control authorities and the public that S. Enteritidis is a known human pathogen and that use of Salmonella-based rodenticides has had severe public health consequences. Effective and safe alternatives to Salmonella-based rodenticides are available worldwide.
